

# SA-TIED Geospatial Analysis Workshop

## Overview

Dr Justin van Dijk

[j.t.vandijk@ucl.ac.uk](mailto:j.t.vandijk@ucl.ac.uk)

# Objectives

We will explore the following topics:

- Fundamentals of using R for data analysis.
- Creating thematic maps using R.
- Quantifying the degree of spatial dependence in a dataset.
- Incorporating space into statistical models.

# Schedule

Day 1 – Morning	R for Data Analysis
Day 1 – Afternoon	R for Spatial Analysis
Day 2 – Morning	Spatial Autocorrelation
Day 2 – Afternoon	Spatial Models

# SA-TIED Geospatial Analysis Workshop

## S04 – Spatial Models

# This session

- Spatial models.
- Geographically weighted statistics.
- Geographically weighted associations.
- More spatial analysis.

# Linear models

- Used to determine the relationship or association between a dependent with one or more independent variables.
- Important assumption: homoscedasticity and independence of residuals.
- Violating this assumption can lead to inefficient estimates and unreliable hypothesis tests.

# Linear models

When building a model based on spatial data:

- Plot the residuals of the linear model to visually inspect for spatial patterns.
- Calculate Moran's I statistic on the residuals to assess spatial autocorrelation.
- If spatial autocorrelation is present, fit a **spatial linear model** to account for it.
- Recalculate Moran's I statistic on the residuals of the spatial model to confirm that the autocorrelation has been addressed.

# Spatial models

A **spatial error model** adjusts for spatial autocorrelation by adding a spatially lagged error term to the regression equation:

$$y = X\beta + v, v = \lambda Wv + \epsilon$$

where  $X\beta$  represents the standard regression components,  $\lambda$  is a spatial autoregressive parameter,  $W$  represents the spatially weights matrix, and  $u$  is a vector of spatially autocorrelated errors.

# Spatial models

A **spatial lag model** incorporates a spatially lagged dependent variable, which is the weighted sum of the dependent variable values in neighboring locations, into the regression equation:

$$\mathbf{y} = \rho \mathbf{W}\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where  $\rho$  is the spatial autoregressive coefficient,  $\mathbf{W}\mathbf{y}$  represents the spatially lagged dependent variable, and  $\mathbf{X}\boldsymbol{\beta}$  represents the standard regression components.

# Spatial models

- Both the spatial error and spatial lag models assume that the relationships between variables are the same across the study area, with adjustments made only for spatial dependencies.
- A Lagrange Multiplier Test can be used to make a decision as to which of these two models is most appropriate.
- What about non-stationarity?

# Spatial models

- Both the spatial error and spatial lag models assume that the relationships between variables are the same across the study area, with adjustments made only for spatial dependencies.
- A Lagrange Multiplier Test can be used to make a decision as to which of these two models is most appropriate.
- What about non-stationarity?

# Geographically weighted statistics

- Unlike traditional global models, which estimate a single set of parameters for the entire study area, geographically weighted statistics allow for parameter estimates that vary across different locations.
- Local means, local standard deviations, local variances.
- Typically uses some **kernel function** to weigh observations based on their distance from the location of interest.

# Geographically weighted statistics

“Everything is related to everything else, but near things are more related than distant things.”

Walter Tobler 1970

# Geographically weighted statistics

Oshan *et al.* 2019

# Geographically weighted statistics

Oshan *et al.* 2019

# Geographically weighted associations

- These ideas can be extended to correlation and regression:
  - Geographically weighted correlation (GWC)
  - Geographically weighted regression (GWR)
- The basic GWR equation is:

$$y_i = \beta_0(v_i, v_i) + \sum_{k=1}^p \beta_k(v_i, v_i) x_{ik} + \epsilon_i$$

- where  $(v_i, v_i)$  are the coordinates of location  $i$  and  $\beta_k(v_i, v_i)$  are the location-specific coefficients.

# Geographically weighted associations

- Each area has its own set of regression coefficients.
- Each location has its own  $R^2$  value.
- Each area has its own standard errors for the coefficient.
- More recently: bandwidths can vary between different variables.

# Questions

# SA-TIED Geospatial Analysis Workshop

More spatial analysis

# More spatial analysis

- Spatial operations.
- Accessibility analysis.
- Geodemographic classification.
- Raster data.
